## 4 1 Introduction

## 5 2 Methods

### 6 2.1 Study system

7 Our study took place in the Lower Fraser Valley in southwestern British  
8 Columbia, Canada, in an agricultural system dominated by mixed veg-  
9 etable, hay, and perennial berry production. From 1984-2018 the Lower  
10 Fraser Valley underwent a 13% decrease in forest patch area, mainly result-  
11 ing from conversion to urban or agricultural land use ([paulTrackingChangesSoil2020a](#)).  
12 .... *decide what else needs to be said in this section later on!*

13 Field surveys were conducted across six replicate landscapes distributed  
14 throughout the Lower Fraser Valley. Each landscape encompassed roughly  
15 3 sq km of farmland interspersed with rural/suburban residence. Land-  
16 scapes were initially chosen to span a gradient of configurational and com-  
17 position diversity metrics, including Shannon's diversity, edge density,  
18 and the ratio of annual to perennial crop cultivation.

19 Thirty sampling transects (50 meters x 2 meters) were established in each  
20 landscape, spaced as evenly as possible based on land-access and the avail-  
21 ability of foraging resources on which to observe bees. We did not survey  
22 in active crop fields except for high-bush blueberry, which offers floral  
23 resources during its spring bloom and can sometimes host other flowers  
24 such as clovers (*Trifolium spp.*) and flatweed (*Hypochaeris radicata*) later in

25 the season. A total of *INSERT TOTAL TRANSECT NUMBER HERE* were  
26 surveyed over the course of two years (2022-2023).

## 27 **2.2 *Bombus* collections and floral surveys**

28 Each landscape was surveyed during 10 sampling rounds in year one  
29 (May-August 2022) and 17 sampling rounds in year two (March-August  
30 2023). During each round of sampling, surveys were conducted on *IN-*  
31 *SERT MEAN PLUS OR MINUS SD OF SAMPLING EFFORT* (mean  $\pm$  SE)  
32 transects.

33 *Bombus* surveys at each transect entailed 5 minutes of active search time  
34 (totaling 140 hours in 2022 and *INSERT TOTAL SAMPLING EFFORT 2023*  
35 in 2023), during which the stopwatch was paused whenever a foraging  
36 bumble bee was sighted. Specimens were captured by netting, placed  
37 into sterile 15 mL tubes, and immediately placed on ice before transfer  
38 to a -80°C freezer at the end of the day. Surveys were conducted on days  
39 when the temperature was above 12°C (10°C for queen surveys) and wind  
40 speeds below 2.5 m/s. In 2022, all *Bombus* species were collected; in 2023  
41 only the focal species (*B. mixtus* and *B. impatiens*) were collected.

42 To assess floral quality, all flowering plants within the transect area were  
43 identified to species or genus level. Abundance estimates were taken for  
44 each species on the log-scale (i.e., 0 = 1-10 inflorescences, 1 = 11-100 in-  
45 florescences, 2 = 101-1000 inflorescences, 3 = 1001-10,000 inflorescences, 4  
46 = 10,000+ inflorescences). Floral survey data was later filtered to exclude

species which bumble bees were never observed visiting (based on over 3,400 visitation events in 2022, and 3,500 visitation events in 2023). This filtering step was included to reduce the noise introduced by a variety of herbaceous weeds with flowers too small to attract or support bumble bee foragers, but which were frequently observed on the transects in high abundance.

### 2.3 Landscape characterization

Land cover maps were developed for each study site based on manual classification of Google Earth satellite imagery (2021) and site visits. Briefly, land cover was classified into 16 categories: annual row crops, blueberry, cranberry, other perennials, polyculture, hay meadows, pasture, fallow, grassy field margins, hedgerows (tree-dominated), hedgerows (blackberry-dominated), forest, wetlands, urban/suburban, roads, and water). These land cover types were chosen based on their hypothesized provisioning of nesting/floral resources and differences in disturbance regimes (see Table ?? for details). Land cover was mapped at 2-meter resolution in QGIS (QGIS\_software).

*INSERT EXPLANATION OF LANDSCAPE METRICS AND HOW WE CALCULATED THEM*

### 2.4 PCR Amplification and Fragment Analysis

DNA was extracted from the mid-leg basitarsus and tarsus (distal tarsus only for queens) using the HOTSHOT protocol (<empty citation>)

Table 1: Description of land cover classifications, including hypothesized resource provisioning for bumble bees. Based on personal observations and expert opinion.

Landcover Class	Description	Vegetation Level	Flowers	Nesting	Disturbance Rank
<b>annual</b>	monoculture annual crops, tilled yearly	bare	sometimes (resource pulse)	no	5
<b>polyculture</b>	mixed annual crops, tilled yearly	bare	sometimes	no	5
<b>hay</b>	multiple cuts per year, tilled every 1-7 yrs	grass	sometimes (clover)	some species	4
<b>fallow</b>	fields taken out of production temporarily	grass	yes	some species	2
<b>pasture</b>	grazed hay meadow	grass	yes	some species	4
<b>blueberry</b>	described in text	woody	yes (resource pulse)	some species	3
<b>cranberry</b>	perennial, flooded yearly	herbaceous	yes (resource pulse)	no	5
<b>other perennial</b>	orchards, tree farms, etc.	woody	sometimes	yes	3
<b>hedgerow (blackberry)</b>	field margins dominated by <i>Rubus armeniacus</i> and <i>R. laciniatus</i>	woody	yes (resource pulse)	yes	2
<b>forest</b>	forest fragments (primarily native species)	woody	yes	yes	1
<b>hedgerow (woody)</b>	planted or remnant hedgerows dominated by trees; planted hedgerows contain flowering species selected for pollinators	woody	yes	yes	2
<b>road/ industrial</b>	paved/impermeable surfaces	bare	no	no	5
<b>grassy margins</b>	unmanaged field margins without woody vegetation	grass	yes	some species	3
<b>suburban/ urban</b>	residential properties, including gardens	woody	yes	yes	4
<b>water</b>	lakes, rivers, irrigation ditches, ocean	bare	no	no	5

69 CITE TRUIT. We utilized the following microsatellite loci from the exist-  
70 ing literature: BT10, BTERN01, BL13, BL15, B126, BTMS0057, BTMS0059,  
71 BTMS0062, BTMS0083 (both species), BTMS0066, BTMS0072, BTMS0086,  
72 BTMS0104, BTMS0126, BTMS0136 (*B. mixtus* only), BT28, BT30, B10, B96,  
73 B124, BTMS0073, and BTMS0081 (*B. impatiens* only) CITE STOLLE, REBER-  
74 FUNK, ESTOUP–CHECK WHICH ESTOUP PAPERS!. One primer for  
75 each locus was individually dye-labelled using 6FAM, NED, PET, or VIC,  
76 and loci were amplified in two multiplex reactions per individual. Each  
77 multiplex reaction contained 4 $\mu$ L of template DNA, 1 $\mu$ L of 10X primer  
78 mix, and 5 $\mu$ L of Qiagen 2X Multiplex PCR Master Mix (Qiagen, Hilden,  
79 Germany). See ?? for plexes and primer concentrations. Diluted PCR  
80 products were submitted for automated fragment sizing at the UBC Se-  
81 quencing and Bioinformatics Consortium (*B. mixtus*) and the Utah State  
82 Center for Integrated Biosystems (*B. impatiens*). 1 $\mu$ L of each sample was  
83 added to 8.85 $\mu$ L of Hi-Di formamide and 0.15 $\mu$ L of LIZ500 size standard;  
84 *B. mixtus* fragments were analyzed on an Applied Biosystems 3730XL 96-  
85 capillary DNA Analyzer and *B. impatiens* fragments were analyzed on  
86 an Applied Biosystems 3730 DNA Analyzer (Applied Biosystems, Foster  
87 City, CA, USA).

88 Scoring error rates were assessed by re-genotyping a panel of 96 individu-  
89 als per species, and loci with observed error rates  $\geq 3\%$  were discarded  
90 from further analyses (BL15 in both species). BTMS0072 was also dis-  
91 carded for *B. mixtus* due to poor amplification and difficulty assigning

92 peak-calls.

## 93 2.5 Colony Assignments

94 We used an iterative approach to assign workers and queens to their na-  
95 tal colonies. First, using the pedigree reconstruction software COLONY  
96 2.0 (CITE JONES AND WANG), we assigned full siblingships based on all  
97 available microsatellite data, assuming male and female monogamy and  
98 no inbreeding. A single run was carried out for each species and year, us-  
99 ing the software’s full-likelihood approach and no siblingship size scaling  
100 or priors. Sibling pairs were maintained when  $P_{fullsibdyad} = 1$ . A sin-  
101 gle individual from each putative colony (including non-circular colonies,  
102 described below) was maintained for downstream analyses of locus qual-  
103 ity.

104 While COLONY can account for inbreeding at the population level, locus-  
105 specific estimates of  $F_{is}$  should generally be similar to one another for a  
106 given population, reflecting their shared evolutionary history. Loci with  
107  $F_{is}$  estimates that deviate significantly from the species mean (across loci)  
108 may suffer from null alleles or other types of scoring errors that can bias  
109 siblingship assignment. We therefore tested individual locus deviations  
110 from population mean  $F_{is}$  as a criterion for marker inclusion/exclusion.

111 Single locus  $F_{is}$  estimates were computed for all site, year, species groups  
112 following CITE WEIR in the package *genepop* [CITE GENEPOP]. The dis-  
113 tributions of  $F_{is}$  estimates for each species at each site can be found in Ap-

114 pendix 1, ??). We then fit linear models to  $F_{is}$  estimates with locus and site  
 115 as fixed predictors. We used sum-to-zero coding so that model intercepts  
 116 represented mean  $F_{is}$  across all loci, and calculated the estimated marginal  
 117 mean of each locus using the *emmeans* package (CITE EMMEANS PACK-  
 118 AGE)(Appendix 1, ??A-B). We iteratively removed loci with  $F_{is}$  signifi-  
 119 cantly different from the species mean  $F_{is}$ , starting with the locus with  
 120 the greatest deviation, and re-running the model after each removal (i.e.,  
 121 because removing a locus with a high or low inbreeding coefficient will  
 122 change the species mean estimate and therefore all comparisons to the  
 123 mean). We did not apply an adjustment for multiple-hypothesis testing,  
 124 but instead utilized a relatively stringent p-value ( $\alpha = 0.01$ ) for removal  
 125 of loci. This process resulted in the removal of loci BTERN01, BTMS0104,  
 126 and BTMS0059 from downstream analyses for *B. mixtus* and removal of  
 127 BTMS0073 and BT28 for *B. impatiens*.  $F_{is}$  estimates for the remaining loci  
 128 ( $n = 10$  for *B. mixtus*,  $n = 13$  for *B. impatiens*) can be found in Appendix 1,  
 129 ??C-D.

130 Next, we checked locus pairs for linkage disequilibrium (LD). Marker link-  
 131 age can lead to non-independent assortment, a condition which violates  
 132 the assumptions of most parentage reconstruction software and can re-  
 133 sult in overconfidence in estimated sibling pairs. LD was calculated for  
 134 each locus pair in each population (site, year, species groups) in *genepop*.  
 135 We applied a Bonferroni correction for multiple hypothesis testing, and  
 136 flagged locus pairs which showed significant deviations in  $> 2$  popula-

137 tions. There was not strong support for linkage disequilibrium between  
138 locus pairs in *B. mixtus*. Four pairs showed signs of LD, but each occurred  
139 at only a single site in a single year. For *B. impatiens*, there was strong  
140 evidence for linkage disequilibrium between BTMS0057 and BL13 (7 out  
141 of 12 populations showed significant LD following Bonferroni correction).  
142 To determine which locus to maintain, we calculated the polymorphic in-  
143 formation content (PIC) using the package *PopGenUtils* CITE TOURVAS  
144 POPGEN UTILS. We found that BTMS0057 had higher PIC in both years  
145 (PIC = 0.78) compared to BL13 (PIC = 0.47 in 2022 and 0.45 in 2023). For  
146 this reason, we chose to maintain BTMS0057 and remove BL13 from fur-  
147 ther analyses for *B. impatiens*.

148 After locus quality screening, we calculated global and pairwise  $F_{st}$  fol-  
149 lowing CITE NEIL 1987 in the package *hierfstat* CITE GOUDET HIERF-  
150 STAT. For both species and years, estimates of global  $F_{st}$  were less than  
151 0.005. Pairwise  $F_{st}$  ranged from -0.002 to 0.01, indicating little or no genetic  
152 differentiation between surveyed sub-populations. Finally, we computed  
153 the marginal mean  $F_{is}$  for each site to determine whether there was evi-  
154 dence for inbreeding following locus removal, and whether it varied be-  
155 tween sites (Appendix 1, ??). Because we found evidence for only minor  
156 inbreeding (e.g.,  $F_{is} < 0.05$ ) we ran all final colony assignments using the  
157 no-inbreeding model. Given the very low estimates of global and pairwise  
158  $F_{st}$ , we chose to combine sites for sibship assignments to maximize the  
159 accuracy of allele frequency estimation.

160 To determine the most effective method for inferring true sibling pairs  
 161 while minimizing falsely inferred pairs,, we tested the performance of  
 162 the COLONY software on simulated datasets using allelic frequencies de-  
 163 rived from our true data (see Appendix 1, Section "Testing COLONY on  
 164 simulated data"). Final assignments were performed based on a single  
 165 COLONY run for each species-year combination, where early-season queens  
 166 from 2023 (defined below) were grouped with workers from 2022. We  
 167 used exclusion tables to prevent the assignment of siblingships between  
 168 individuals originating from different sites, based on our intuition that  
 169 such relationships would be highly unlikely due to species biology and  
 170 the fact that potential foraging area increases as the square of foraging ra-  
 171 dius (see Appendix 1, Section "Observing colony mates at multiple sites"  
 172 for support). Each run assumed male and female monogamy and no in-  
 173 breeding, and utilized an informative prior on siblingship size ( $n = 1$ , e.g.,  
 174 approximately the harmonic mean of expected siblingship sizes) but no  
 175 siblingship size scaling. All runs were performed using the Linux com-  
 176 mand line version of the software, with run length set to "long", likelihood  
 177 set to "full-likelihood" and precision set to "high precision." Sibling pairs  
 178 were maintained with  $P_{fullsibdyad} = 1$ . To account for non-circular fami-  
 179 lies (e.g., individual A related to individual B, B related to C, but A *not*  
 180 related to C) we maintained "missing-links" (e.g., A related to C in the ex-  
 181 ample above) when  $P_{AC} > 0.95$ . If the missing link was rejected at the  
 182 95% confidence threshold, we maintained the largest possible clique (all

183 individuals related), using a random draw in cases where the two remain-  
184 ing cliques were of equal size. In total this resulted in the loss of XXX  
185 highly probable sibling pairs in *B. mixtus* and XXX pairs in *B. impatiens*.  
186 We acknowledge the violations on the assumption of male and female  
187 monogamy may result in a heightened number of false-negatives while  
188 using the monogamous specification in COLONY—however, our simu-  
189 lations showed clearly that our dataset was not sufficient to distinguish  
190 half-sib relationships, and allowing for polyandry resulted in a very high  
191 rate of falsely-inferred sibling pairs.

### 192 **3 Results**

### 193 **4 Discussion**
